

# **Module 1 — Read 0**

**Project preview — Project 1 — Testing a Claim**

# Module 1 Preview

**Big question:** Is what we observed **surprising**?

**i** Note

This page is a **short orientation**, not the textbook. Read before **Read 1** so you see how Project 1 fits the course story (five steps, three worlds, and “theory before data”).

## Good science: state your claim before you observe

In **Module 0, Read 0** you met the **five-step statistical process**. Project 1 is your first full pass through it.

| Step                | In Project 1                                                                                                                                                         |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 — <b>Ask</b>      | A clear research question about a <b>proportion</b> $p$ (probability of success on one trial)                                                                        |
| 2 — <b>Plan</b>     | Define $p$ , write $H_0$ and $H_a$ , decide how you will analyze and conclude — <b>before</b> you collect all $n = 25$ trials ( <b>milestone</b> )                   |
| 3 — <b>Collect</b>  | Observe the process; record $x$ successes out of $n$                                                                                                                 |
| 4 — <b>Analyze</b>  | Describe what you saw; compare $x$ to the <b>null model</b> you planned under $H_0$ ; compute a <b>p-value</b>                                                       |
| 5 — <b>Conclude</b> | Interpret the p-value in context on a one-page report and make a conclusion about the answer to your research question based on the data you collected and analyzed. |

**Best practice:** Step 2 comes **before** Step 3. Good scientists do not pick  $H_0$  after seeing the data  $x$ . Instead they state the claim they want to test, build the imagined model, *then* gather data. This best practice is reinforced by doing **Phase A before Phase B** on the project page and in the [milestone notebook](#).

## Three worlds — in the right order

Statistics moves among three worlds (**Module 0**). For Project 1, the order matters:

### 1. The world we imagine (theory first)

Here you work with claims and models, not your dataset yet.

- Turn your research question into  $H_0$  and  $H_a$  with theorized value for  $p$  in  $H_0$ .
- Pretend  $H_0$  is true: if the null proportion were correct, what counts  $X$  of successes in  $n$  trials would be typical?
- That pretend world is a binomial model: fixed  $n$ , fixed  $p$  from  $H_0$ , independent binary trials.

Your **milestone null plot** (step A5) is a picture of this imagined world, drawn before you know your observed value  $x$ .

### 2. The world we observe (observations second)

Only after the plan do you collect data.

- Run  $n = 25$  trials from a process that satisfies the **four BRP conditions**.
- Record  $x$  = number of successes and find  $\hat{p} = x/n$ .

- Descriptive charts (bar or pie) describe what happened, they do not test the claim by themselves.

### 3. The world of computers (connect the two)

The programming language R help us move between what we imagine and what we observe:

- `dbinom + geom_col` compute bar heights and show them for  $P(X = x)$  under  $H_0$
- `geom_vline` — mark your observed  $x$  on that null plot
- `pbinom` — p-value summarizes how unusual your observed  $x$  is if the  $H_0$  you imagined were actually true, relative to the  $H_a$  you imagined.

You will take a deep dive into the mathematics of the theoretical world in [Read 1](#) and how to use it to test your observation in [Read 2](#).

## Observation meets theory: the p-value

Once you have planned the model and collected  $x$ , you ask:

If the world I imagined under  $H_0$  were true, how often would I see a count as or more extreme than my observed  $x$  (in the direction of  $H_a$ )?

That probability is the p-value.

- A **small** p-value means your  $x$  would be **unusual** if  $H_0$  were true — the observed data and the null claim do not fit well.
- A **large** p-value means your  $x$  is **plausible** under  $H_0$  — the data are consistent with the null model (not proof that  $H_0$  is true).

**!** One mistake to avoid early

The **p-value is not** the probability that  $H_0$  is true. It is the probability of data **at least this extreme**, *assuming*  $H_0$  is true.

## A deep dive

Most inferential methods in later modules rely on approximations or software you will be asked to use based on trust. Project 1 is different: the binomial test is one of the few cases where, with high-school algebra and patience, you can understand the whole story, from assumptions through the probability formula to the p-value.

We will build it up in [Read 1](#) and [Read 2](#):

1. Probability language (events,  $p$ , independence).
2. The binomial pmf — exact probability for each possible count  $x$ .
3. The four BRP conditions — when that formula applies to your real process.
4. Hypotheses, null plots, and p-values in context.

At the end of the module you will use just one line of code (`pbinom()` in R) to compute a p-value but you will have a deep understand of exactly what this line is computing, how to interpret it and when to use it.

## The binomial probability formula (preview)

Let  $X$  = number of successes in  $n$  independent trials, each with the same probability  $p$  of success. Under that model,

$$P(X = x) = \binom{n}{x} p^x (1 - p)^{n-x}, \quad x = 0, 1, \dots, n$$

Read this as: choose which  $x$  of the  $n$  trials are successes ( $\binom{n}{x}$  ways), multiply success probability  $p$  on those  $x$  trials and failure probability  $(1 - p)$  on the remaining  $n - x$  trials.

For Project 1 you plug in  $n = 25$  and  $p$  from  $H_0$  to draw the **null distribution**. Your observed  $x$  is a single bar on that picture; the **p-value** is the total probability in the tail(s) at least as extreme as  $x$  toward  $H_a$ .

## Four BRP conditions

Your data collection must satisfy a **binomial random process** (BRP). You will defend all four in your report; check them in context.

| Condition                       | Meaning (in your study)                                                           |
|---------------------------------|-----------------------------------------------------------------------------------|
| (a) <b>Binary</b>               | Each trial has exactly two outcomes (success / failure)                           |
| (b) <b>Independent</b>          | One trial does not change the chance of success on another                        |
| (c) <b>Fixed <math>p</math></b> | The probability of success is the same on every trial (under $H_0$ for the model) |
| (d) <b>Fixed <math>n</math></b> | You decide the number of trials in advance (Project 1 uses $n = 25$ )             |

If any condition fails, the binomial formula (and `pbinom`) do not describe your process honestly.

## What you will do in practice

| Phase                       | You understand...                                    | You compute with...                                               |
|-----------------------------|------------------------------------------------------|-------------------------------------------------------------------|
| <b>Plan (milestone)</b>     | Question, $p$ , $H_0/H_a$ , BRP, null plot           | <code>dbinom</code> + <code>geom_col</code> (no $x$ yet)          |
| <b>Collect</b>              | One real $x$ from your process                       | Your own data                                                     |
| <b>Analyze &amp; report</b> | Descriptive $\hat{p}$ ; tail probability under $H_0$ | <code>geom_vline</code> , <code>pbinom</code> , one-page write-up |

## Tour the sample project

Open the **sample one-page write-up — ESP binomial test (PDF)**. It is a finished Project 1 report.

| Section                       | What to notice                                                           | World                       |
|-------------------------------|--------------------------------------------------------------------------|-----------------------------|
| <b>Introduction</b>           | Question, motivation, $p$ in context, $H_0$ and $H_a$ stated before data | Imagine                     |
| <b>Data collection</b>        | How, when, where; <b>four BRP conditions in context</b>                  | Observe                     |
| <b>Descriptive statistics</b> | $x$ , $n$ , $\hat{p}$ , chart of observed counts                         | Observe                     |
| <b>Inferential statistics</b> | Null binomial plot, line at $x$ , p-value from <code>pbinom</code>       | Imagine + computer          |
| <b>Conclusion</b>             | What the p-value means for the question (not “accept $H_0$ ”)            | Imagine (but more accurate) |

## What you will do (your project, not ESP)

By the end of Module 1 you will:

1. Choose your **own** binomial process ( $n = 25$ ), not ESP or other course examples.
2. Complete the **milestone** — theory and null plot **before** full data collection.
3. Collect data, then analyze with R and write a **one-page** report (**rubric**).
